<u>Le</u>	cture	2 7	<u>:</u>	08/	15/	22

Example 4.8:

Market data:

bond principal	maturity (years)	annual coupon	Price
100	0.25	0	99.6
(00)	0.5	0	99.0
(00	1	0	97.8
(00)	1.5	4	102.5
(00)	2	S	105.0

Implied annual n-year zero rates (cont. comp.):

Notation: 10(n) = today's n-year spet rate

N=0.25: 100. C-7.(0.25).0.25 = 99.6

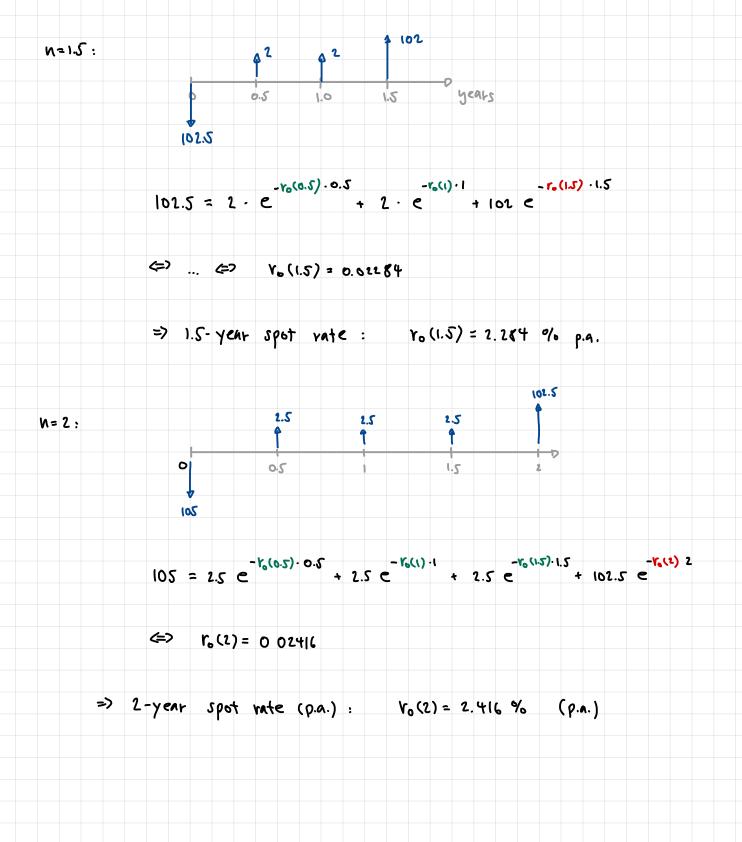

(=) $r_0(0.25) = (69(\frac{106}{99.6}) \cdot \frac{1}{0.25} = 0.01603$

=7 3- month spot rate (p.a.): ro(0.25)=1.603 % p.a.

=> G-mouth spot rate (p.a.): r. (0.5) = 2.010 % p.a.

N=1: $100 e^{-\frac{r_6(1)}{1}} = 97.8$ (=) $r_6(1) = ... = 0.02225$

=> 1-year spot rate (p.a.): Vo(1) = 2.225 % p.a.

Interpolated linearly between given maturities, and assume curve to be flat before maturity 0.25 and after maturity 2.

Determination of torward rates:

$$n=2: \int_{0}^{\infty} (1,2) = \frac{2}{3}$$

It must hold true: From today's perspective

"no arbitrage"

$$(=)$$
 $Y_{6}(2) \cdot 2 = Y_{6}(1) \cdot 1 + f_{6}(1,2) \cdot 1$

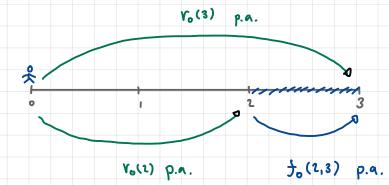

$$(=)$$
 $\int_{0}^{1} (1,2) = \frac{Y_{0}(2) \cdot 2 - Y_{0}(1) \cdot 1}{2 - 1}$

- (i): borrow @ ro(2) for two years and invest @ ro(1)

 for year 1 and @ fo(1,2) for year 2
- invest

 ((i): borrow @ r.c.) for two years and invest @ r.c.)

 for year 1 and @ f.(1,2) for year 2

General formula:

$$f_o\left(T_1,T_2\right) = \frac{\gamma_o(T_2) \cdot T_2 - \gamma_o(T_1) \cdot T_1}{T_2 - T_1}$$
